Programming Assignment 8: Pricing an American-Option via Trinomial Trees

Due Date: 8 November 2019

© Prof. R.S. Sreenivas

1 Trinomial Trees and Lattices

Pretty much everything parallels the Binomial Tree from a conceptual sense. If the stock price at discrete time step k is denoted by S_k . In this case, the process S_k is specified as

$$S_{k+1} = \begin{cases} uS_k & \text{with probability } p_u, \\ \frac{S_k}{u} & \text{with probability } p_d, \\ S_k & \text{with probability } 1 - p_u - p_d. \end{cases}$$

Just as with the binomial tree whose leaves can be combined to form the binomial lattice, you can get a *trinomial lattice* from a trinomial tree. To ensure the martingale property

$$E\{S_{k+1} \mid S_k\} = R \times S_k,$$

where $R = e^{r\frac{T}{n}}$, as with the Binomial Tree. We need to assign¹

$$u = e^{\sigma \sqrt{2(T/n)}}$$

$$p_u = \left(\frac{\sqrt{R} - \frac{1}{\sqrt{u}}}{\sqrt{u} - \frac{1}{\sqrt{u}}}\right)^2$$

$$p_d = \left(\frac{\sqrt{u} - \sqrt{R}}{\sqrt{u} - \frac{1}{\sqrt{u}}}\right)^2$$

Just as with the binomial lattice. you can use (k,i) to denote an arbitrary vertex on the trinomial lattice. The vertex (k,i) is connected to $\{(k+1,i+1),(k+1,i),(k+1,i-1)\}$ with the appropriate probabilities along the appropriate arcs. If V(k,i) is value of the option at (k,i), for the european call option we have the recursion

$$V(k,i) = \left\{ \begin{array}{ll} \max\{0, S_0 \times u^i - K\} & \text{if } (k,i) \text{ is a terminal node} \\ \frac{p_u \times V(k+1,i+1) + (1-p_u-p_d) \times V(k+1,i) + p_d \times V(k+1,i-1)}{R} & \text{otherwise} \end{array} \right.$$

The option price is V(0,0).

You are going to do a little more than this for this programming assignment.

¹You can verify this at your leisure.

2 Part 1: Pricing an American-Option using a Trinomial Model by Recursion

Using my C++ program american_option_pricing_by_binomial_model.cpp on Compass as reference, write a C++ program that takes as command-line input the values of T, N, r, σ, S_0 and K, and presents the value of an *American-Option* using a trinomial model.

Input: The command-line input is the same as what I have for the C++ code that priced the European option in lesson 6 of my notes.

Output: A sample output that I expect from your code is shown in figure ??

```
Recursive Trinomial American Option Pricing
Expiration Time (Years) = 0.5
Number of Divisions = 20
Risk Free Interest Rate = 0.05
Volatility (%age of stock value) = 30
Initial Stock Price = 50
Strike Price = 40
R = 1.00125
Up Factor = 1.06938
Uptick Probability = 0.250935
Downtick Probability = 0.249067
Notick Probability = 0.499998
Trinomial Price of an American Call Option = 11.5491
Trinomial Price of an American Put Option = 0.570673

```

Figure 1: Sample output (**Note**: 20 divisions will take some time to run on your computer. Be patient. The next part of this assignment will be able to handle a large number of divisions, as you will see.).

3 Part 2: Pricing an American-Option using a Trinomial Model by Dynamic Programming

Using my C++ program american_option_pricing_by_dynamic_programming.cpp on Compass as reference, write a C++ program that takes as command-line input the values of T, N, r, σ, S_0 and K, and presents the value of an American-Option using a trinomial model.

Input: The command-line input is the same as what I have for the C++ code that priced the European option in lesson 6 of my notes.

Output: A sample output that I expect from your code is shown in figure ??

```
